

# User Guide: Forensic Medical Database Management System

Welcome to the **Forensic Medical Database Management System (FMDMS)**. This system is designed to streamline the management of clinical, mortuary, and forensic data securely and efficiently.

This guide will help you understand the core modules, user roles, and how to navigate the application.

---

## 1. Introduction

The FMDMS replaces manual record-keeping with a secure, centralized database. It handles living clinical examinations, post-mortem cases, hospital and ward logistics, and system administration.

---

## 2. User Roles & Access Levels

Access to the system is strictly controlled based on your assigned role and access level.

### Roles

- **Admin:** Has full control over the system, including managing hospitals, wards, doctors, and system user accounts.
- **JMO (Judicial Medical Officer):** Has full access to clinical and deceased records, autopsies, evidence logging, and reporting.
- **Nurse:** Has access to basic patient registration, data entry, and view-only permissions for authorized reports.

### Access Levels

- **Standard:** Can view and create standard records.
  - **Elevated:** Can edit and manage records within their designated department.
  - **Full:** Can delete records, generate system-wide reports, and manage database settings.
- 

## 3. Core Modules & Navigation

Use the left-hand sidebar to navigate between different sections of the system.

## 3.1 Patient Management

**Path:** Dashboard > Patients

This module is used to register and manage living individuals undergoing clinical forensic examinations. - **Register Patient:** Captures demographic details, contact information, and assigns the patient to a specific Hospital and Ward. - **Hospital/Ward Assignment:** The system uses **Smart Dropdowns** to prevent errors. When you select a hospital, the Ward dropdown automatically filters to only show wards belonging to that specific hospital. - **View Profiles:** Access full medical histories, clinical findings, and injury reports linked to a patient.

## 3.2 Mortuary & Deceased Management

**Path:** Dashboard > Deceased / Body Identification

Manages all records related to post-mortem examinations. - **Register Deceased:** Logs case details, date/place of death, and BHT numbers. - **Next of Kin:** Links relatives to the deceased for identification and legal purposes. - **Body Identification:** Tracks the chain of custody and identification status of unidentified bodies.

## 3.3 Infrastructure Management

**Path:** Dashboard > Hospitals / Wards / Doctors

*(Admin & Elevated Access Only)* - **Hospitals:** Register new hospitals into the system framework. - **Wards:** Assign wards to specific hospitals. **Note:** A ward must be linked to a valid hospital ID. - **Doctors:** Maintain a directory of medical staff, including their SLMC Registration Numbers and designations.

## 3.4 System Users Directory

**Path:** Dashboard > System Users

*(Admin Access Only)* - **Add User:** Create login credentials (Username, Password, Role, Access Level) for staff. - **Decoupled Architecture:** Creating a system user solely creates a software login account. If the staff member is a doctor, their professional details must be added separately in the **Doctors** module.

---

## 4. Best Practices & Data Integrity

To ensure the database remains fast, accurate, and reliable: 1. **Never Share Passwords:** Audit logs track actions back to the specific User\_ID that performed them. 2. **Use Dropdowns:** Always use the provided dropdowns (like Blood Group, Gender, Hospital, and Ward) rather than attempting to force manual text. 3. **Handle Errors Gracefully:** If a

patient cannot be assigned to a ward, check the **Wards** module to ensure that ward is properly registered to the selected hospital.

## 5. First-Time Setup

To run this system on a completely new computer without risking a database crash or needing to manually import .sql files via MySQL Workbench, follow these simple steps:

1. **Install Prerequisites:** Ensure the new PC has **MySQL Server** and **Node.js** installed.
2. **Setup the Database Credentials:** Open the .env file in the Backend folder and update the DB\_PASSWORD (and other DB settings) to match the MySQL installation on the new machine.
3. **Initialize the Database:**
  - Open a terminal in the Backend folder.
  - Run the command: `npm run init-db`
  - *This script will safely and automatically create the database schema, tables, relationships, and advanced stored procedures from scratch.*
4. **Start the Application:**
  - Run `npm start` in the Backend folder to start the API.
  - Run `npm run dev` in the Frontend folder to launch the web interface.
